- Structural Models for IS Architectures
- IS Architecture Concepts

# Requirements for the Structure of IS Architectures

- Minimisation of complexity for IS Components
- Scalability of IS components
- Portability of IS components
- Maintainability of IS components
- Standardisation of IS components
- Well-defined interfaces between IS components
- Independence of IS components

Modularisation of IS components

#### **Three-Tier Concept**

# Three-Tier Concept Example (2)

#### Presentation tier

The top-most level of the application is the user interface. The main function of the interface is to translate tasks and results to something the user can understand.

#### Logic tier

This layer coordinates the application, processes commands, makes logical decisions and evaluations, and performs calculations. It also moves and processes data between the two surrounding layers.

#### Data tier

Here information is stored and retrieved from a database or file system. The information is then passed back to the logic tier for processing, and then eventually back to the user.

# Summary on Three-Tier and MVC Concept

- Similar concepts for structuring IS architectures
- Neither one of the concepts is universally defined or specified, e.g.
  - Two-tier concepts are also in existence (two-tier architecture)
  - Program logic resides sometimes in the model and other times in the controller (MVC architecture)

#### In conclusion:

Independent of the underlying structural models for IS architectures, make sure to modularise certain categories of functionality in an IS.

- IS Architecture Concepts

## Architecture Concepts of Networked IS

- Central Server Architecture Low-feature terminals (receiver of services) attached to a powerful central computing unit (provider of services)
- Client / Server Architecture Network of computers, which can take the role of a server (provider of services), a client (receiver of services) or both.
- Cloud Computing Architecture Network of computers in the role of a client (receiver of services) connected to a "cloud" of computers (provider of services), which act as a single central server
- Peer-to-Peer Architecture Network of computers holding equal rights (provider / receiver of services)
- Edge Computing Architecture
   Leverages network resources to optimise cloud computing systems by
   performing data processing at the edge of the network, near the data source

#### **Central Server Architecture**

- One powerful central computer
- "Dumb" low-feature terminals (often even without hard drive)
- Terminals provide only the graphical user interface (GUI)
- Central server in charge of processing applications
- Central server takes care of database and its management

# Review of the Central Server Architecture Concept

#### Advantages

- Central, common data storage
- Homogenous application environment
- No terminal administration required
- Low-cost terminals

#### Disadvantages

- Single point of failure
- Fixed network structure
- Monolithic
- Cost-intensive central servers
- Problematic in case of huge traffic and amounts of data

- MVS
- z/OS
- •

#### Client/Server Architecture

#### Client/Server Architecture Along the mobile business **Three-Tier Structural Concept** Server Terminal Fileserver emulation LAN Distributed Remote Distributed Distributed Remote Fileserver Central server presentation presentation application database database Source: Based on Hennekeuser, 2004 D D D D Network- interface Ρ D Ρ Ρ P

Local workstation

#### **Distributed Presentation**

Division of the presentation between server and client:

- Abstract part of the presentation (server)
   Objects (e.g. a window) are created in an abstract manner, i.e. without any concrete representation and functionality.
- Platform-specific part of the presentation (client) Abstract objects are created and represented in a platform-specific manner (e.g. making use of the platform's GUI).
- Advantages of this approach Heterogeneous application systems can be integrated into a unified user interface or used on different platforms.
- Examples:
  - X-Windows: A user interface using X-Windows can be represented on multiple platforms.
  - Mobile Web App within Native App: Spiegel Online

Server

Distributed presentation

#### **Remote Presentation**

Presentation is outsourced to the client:

- Outsourcing of the presentation to the client is especially beneficial, if the central server has no own user interface.
- Clients are able to run on several different platforms.
- User interfaces can be individually customised according to users' needs (e.g. GUI).
- Client can not be a "dumb" terminal.
- Examples:
  - Citrix XenDesktop
  - TeamViewer
  - Apple Airplay

#### Server

Remote presentation

#### Client

# **Distributed Application**

Division of the application functions (logic) between server and client:

- Centrally used application functions are hosted on the server in order to be available for everyone.
- Decentralised applications reside on the respective client.
- Central application functions will only be used on demand.
- Advantages: Development and maintenance of application functions get simplified; complexity is reduced.
- Examples:
  - Groupware
  - Facebook App
  - DB Navigator App
  - Siri

Server

Distributed application

#### **Remote Database**

Data management resides on the server:

- Traditional approach for database applications
- Multiple application systems use the same database.
- Data management can also be distributed across multiple servers.
- Problem: There are several implementations of the popular database query language "SQL" with many proprietary extensions and differences.
- Examples:
  - Customer Information System
  - Dropbox App
  - DB Navigator App (previously)

Server

Remote database

Client

### **Distributed Database**

Data management is distributed between server and client:

- Two incarnations of a distributed database exist:
  - Partitioning of data storage between server and client
    - Organisational structure: Centralised directory of an enterprise vs. personal address book
    - Frequency of use: Current business figures vs. archive
    - Access time: Current stock market values vs. archive
    - ...
  - Partitioning of database management system (DBMS) between server and client
    - Data access functionality (frequently used) on the client
    - Database administration (less frequently used) on the server
    - Examples:
      - Here Maps App
      - Navigon App

Distributed database

Server

# Review of the Client/Server Architecture

- Advantages
  - Can be designed and extended flexibly
  - High interaction and communication capabilities
  - Dependability through redundant resources

#### Disadvantages

- High server workload because of multi-user access
- High planning and coordination efforts
- High network bandwidth required
- High administrative workload

# **Cloud Computing Architecture**

Internet-centric computing architecture:

- Providers are offering complex services based on hard- and software in an abstract form.
- Storage, computing power, or complex services can be accessed by client via defined interfaces via the Internet.
- Underlying hard- or software of a cloud is not relevant for a client.
- Types of cloud computing services
  - Infrastructure as a service
  - Platform as a service
  - Software as a service
- Providers, e.g.
  - Amazon, Google, Microsoft, Deutsche Telekom, etc.

# Cloud Computing Architecture

- Advantages
  - Information systems become highly scalable.
  - Central data storage and backup
  - Cost efficient (one has only to pay for the actually used computing power and time)
  - Anytime, anywhere access to applications and data
  - Allows to run sophisticated applications on low-powered systems (e.g. mobile devices' voice recognition systems)

#### Disadvantages

- Enterprises or end users have to rely on the cloud service provider and the legal and political environment.
- Potential threats
  - Data leakage
  - Data unavailability
  - Provider bankruptcy, lock-in effects
  - Internet connection failures

#### Peer-to-Peer Architecture

#### Network of computers with equal capabilities

- Properties
  - No central instance coordinating the required interactions
  - No centralised database
  - Peers act autonomically.
  - Each peer is only aware of those other peers it is currently communicating with.
  - Peers, connections, and information flows within this concept are not guaranteed.
- Advantage
  - Required resources are provided by many parties (e.g. for the distribution of large files)
- Disadvantages
  - High complexity
  - Requires critical mass of peers

# Edge Computing Architecture

Pushing "intelligence" to the edge of the network

- Why edge computing?
  - Proliferation of IoT devices producing data to be processed
  - Limitations due to centralized nature of cloud architectures
  - Clouds' quality of service impacted by distance to data center
  - Steady decline in the cost of processing power & appearance of intelligent endpoint devices that sense and can make inferences
- What is edge computing?
  - Distributed approach to computing at/near network-endpoints
  - Heterogeneous nomenclature [edge (2004-), fog (2012-) and mist (2015-) computing] due to multiple interests and approaches
  - None of them synonymous with cloud computing

# Edge Computing Architecture: Advantages and Applications

- Lower core network load and transmission costs since less / pre-processed data is transmitted
- Reduced load on cloud server / data centre and more efficient resource use possible
- Reduced latency key enabler of use-cases like autonomous driving
- New functionalities provided by intelligent endpoint devices

## Edge Computing Architecture: Disadvantages

- Security challenges
  - Distributed architecture increases number of attack vectors.
  - The more "intelligent" the device, the more vulnerable to infections and exploits (e.g. integrated webserver)
  - IP address spoofing, man-in-the-middle attacks
- Trust and authentication concerns
- Risk of a configuration drift when inferior device management solutions are implemented
- Fixed physical location and cost of hardware
- "Hidden" licensing costs of endpoint devices (base version vs. additional functionalities)
- Sometimes adding unnecessary overhead and complexity to the system, as not always needed for IoT applications
